Photosynthesis is the process by which green plants use light energy to make glucose from carbon dioxide and water. The light dependent reactions occur in the thylakoid membranes, where water is split, releasing oxygen. The Calvin cycle takes place in the stroma and uses ATP and NADPH to fix carbon dioxide. Photosynthesis is the process by which green plants use light energy to make glucose from carbon dioxide and water. The light dependent reactions occur in the thylakoid membranes, where water is split, releasing oxygen. The Calvin cycle takes place in the stroma and uses ATP and NADPH to fix carbon dioxide.
